

# The Code Thus Far..

In this lesson, we will take a look at the code we have created so far.

Let's take a breath and pause to check what the code for the neural network class we're building up looks like. It should look something like the following.

```
1  # neural network class definition
2  class neuralNetwork:
3
4
5      # initialise the neural network
6      def __init__(self, inputnodes, hiddennodes, outputnodes, learningrate):
7
8          # set number of nodes in each layer
9          self.inodes = inputnodes
10         self.hnodes = hiddennodes
11         self.onodes = outputnodes
12
13         # link weight matrices, w11 w12 ... w21 w22 etc
14         # weights inside the arrays are 0 and 1 by default
15         self.wih = numpy.random.random((self.inodes, self.hnodes))
16         self.who = numpy.random.random((self.hnodes, self.onodes))
17
18         # learning rate
19         self.lr = learningrate
20
21         # activation function: sigmoid
22         self.activation_function = lambda x: 1 / (1 + numpy.exp(-x))
23
24         pass
25
26
27
28     # train the neural network
29     def train():
30         pass
31
```

That is just the class, aside from that we should be importing the `numpy` and `scipy.special` modules right at the top of the code in the cell below:

```
1  import numpy
2  # scipy.special for the sigmoid function expit()
3  import scipy.special
```

It is worth briefly noting the `query()` function only needs the `input_list`. It doesn't need any other input.

That's good progress, and now we look at the missing piece, the `train()` function. Remember there are two phases to training, the first is calculating the output just as `query()` does it, and the second part is backpropagating the errors to inform how the link weights are refined.
