Code Vectorization

Introduction

Uniform Vectorization

Coding Example: Game of life (Python approach)

Coding Example: Game of life (NumPy approach)

Coding Example: Reaction-Diffusion

Temporal Vectorization

Coding Example: The Mandelbrot Set (Python approach)

Coding Example: The Mandelbrot

Introduction

This lesson gives a brief introduction to code vectorization and explains an example using pure Python and NumPy.

We'll cover the following

- What is Code vectorization?
- Example
- Solution 1: Pure Python
- Solution 2: Use np.add(list1,list2)
- Compare time of two approaches

What is Code vectorization?

Code vectorization means that the problem you're trying to solve is inherently vectorizable and only requires a few NumPy tricks to make it faster. Of course, it does not mean it is easy or straightforward, but at least it does not necessitate totally rethinking your problem (as it will be the case in the **Problem vectorization** chapter). Still, it may require some experience to see where code can be vectorized.

Example

Let's illustrate this through a simple example where we want to **sum up two lists of integers**.

Solution 1: Pure Python

One simple way using pure Python is:

```
1 def add_python(Z1,Z2):
2     return [z1+z2 for (z1,z2) in zip(Z1,Z2)]
```

Solution 2: Use np.add(list1,list2)

This first naive solution can be vectorized very easily using NumPy:

```
1 def add_numpy(Z1,Z2):
2     return np.add(Z1,Z2)
```

Compare time of two approaches

Without any surprise, benchmarking the two approaches shows that the second method is the fastest with one order of magnitude.

main.py

tools.py

```
1 import random
2 import numpy as np
3 from tools import timeit
4
5 def add_python(Z1,Z2):
6     return [z1+z2 for (z1,z2) in zip(Z1,Z2)]
7
8 def add_numpy(Z1,Z2):
9     return np.add(Z1,Z2)
10
11 Z1 = random.sample(range(1000), 100)
12 Z2 = random.sample(range(1000), 100)
13
14 timeit("add_python(Z1, Z2)", globals())
15 timeit("add_numpy(Z1, Z2)", globals())
16
17
```

RUN

SAVE

RESET

Output

1.278s

1000 loops, best of 3: 21.9 usec per loop
1000 loops, best of 3: 54 usec per loop

Not only is the second approach faster, but it also naturally adapts to the shape of **Z1** and **Z2**. This is the reason why we did not write **Z1 + Z2** because it would not work if **Z1** and **Z2** were both lists. In the first Python method, the inner **+** is interpreted differently depending on the nature of the two objects such that if we consider two nested lists, we get the following outputs:

```
1 import numpy as np
2
3 def add_python(Z1,Z2):
4     return [z1+z2 for (z1,z2) in zip(Z1,Z2)]
5 def add_numpy(Z1,Z2):
6     return np.add(Z1,Z2)
7
8 Z1 = [[1, 2], [3, 4]]
9 Z2 = [[5, 6], [7, 8]]
10 print("Using concatenation:",Z1 + Z2)
11     #[[1, 2], [3, 4], [5, 6], [7, 8]]
12 print("Using pure python:",add_python(Z1, Z2))
13     #[[1, 2, 5, 6], [3, 4, 7, 8]]
14 print("Using numpy.add:",add_numpy(Z1, Z2))
15     #[[ 6  8][10 12]]
```

RUN

SAVE

RESET

Output

0.786s

Using concatenation: [[1, 2], [3, 4], [5, 6], [7, 8]]
Using pure python: [[1, 2, 5, 6], [3, 4, 7, 8]]
Using numpy.add: [[6 8]
[10 12]]

Summing up, the first method concatenates the two lists together, the second method concatenates the internal lists together and the last one computes what is (numerically) expected.

Solve this Quiz!

Q

Which of the following is a good approach when designing a solution to a problem?

☐ A) Think of a brute force Python solution

☒ B) Think of vectorization using NumPy tricks
