

Dependency Diagrams

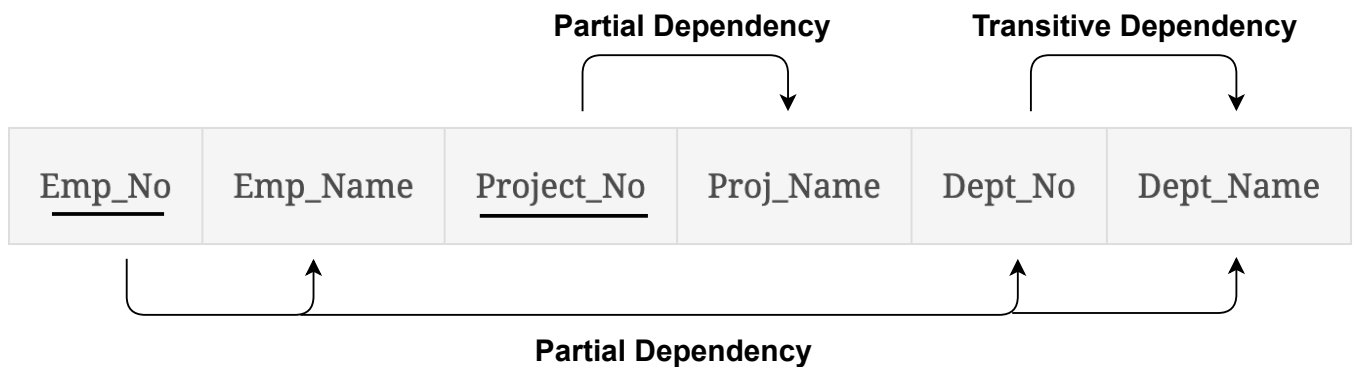

In this lesson, we will look at the diagrammatic representation of functional dependencies.

We'll cover the following

- Dependency diagrams

Dependency diagrams

A dependency diagram illustrates the various dependencies that might exist in a **non-normalized** table. A non-normalized table is one that has data redundancy in it. This is illustrated below:

An example of a dependency diagram

As we can observe from the table above, **Project_No** and **Emp_No**, combined, are the primary key (as the combination of these two attributes can be used to identify each record uniquely).

The following dependencies can be identified from this table:

Partial dependencies:

- **Project_No** → **Proj_Name**

Reason: Since the name of the project is only dependent upon part of the

multi-attribute PK, i.e., Project_No, this results in partial dependency.

- $\text{Emp_No} \rightarrow \text{Emp_Name}, \text{Dept_No}$

Reason: Similar to the example above, we see that these two attributes only depend on part of the composite key and not the whole.

Transitive dependency:

- $\text{Dept_No} \rightarrow \text{Dept_Name}$

Reason: Since a non-key attribute (Dept_Name) is dependent on another non-key attribute (Dept_No), this results in a transitive dependency.

We have highlighted some of the dependencies that exist in this table, but there are many more.

The next lesson will include a short quiz to test your knowledge of functional dependencies.
