## CountDownLatch

## CountDownLatch

CountDownLatch is a synchronization primitive that comes with the java.util.concurrent package. It can be used to block a single or multiple threads while other threads complete their operations.

A CountDownLatch object is initialized with the number of tasks/threads it is required to wait for. Multiple threads can block and wait for the CountDownLatch object to reach zero by invoking await(). Every time a thread finishes its work, the thread invokes countDown() which decrements the counter by 1. Once the count reaches zero, threads waiting on the await() method are notified and resume execution.

The counter in the <code>CountDownLatch</code> cannot be reset making the <code>CountDownLatch</code> object unreusable. A <code>CountDownLatch</code> initialized with a count of 1 serves as an on/off switch where a particular thread is simply waiting for its only partner to complete. Whereas a <code>CountDownLatch</code> object initialized with a count of N indicates a thread waiting for N threads to complete their work. However, a single thread can also invoke <code>countDown()</code> N times to unblock a thread more than once.

If the <code>CountDownLatch</code> is initialized with zero, the thread would not wait for any other thread(s) to complete. The count passed is basically the number of times <code>countDown()</code> must be invoked before threads can pass through <code>await()</code>. If the <code>CountDownLatch</code> has reached zero and <code>countDown()</code> is again invoked, the latch will remain released hence making no difference.

A thread blocked on await() can also be interrupted by another thread as long as it is waiting and the counter has not reached zero.

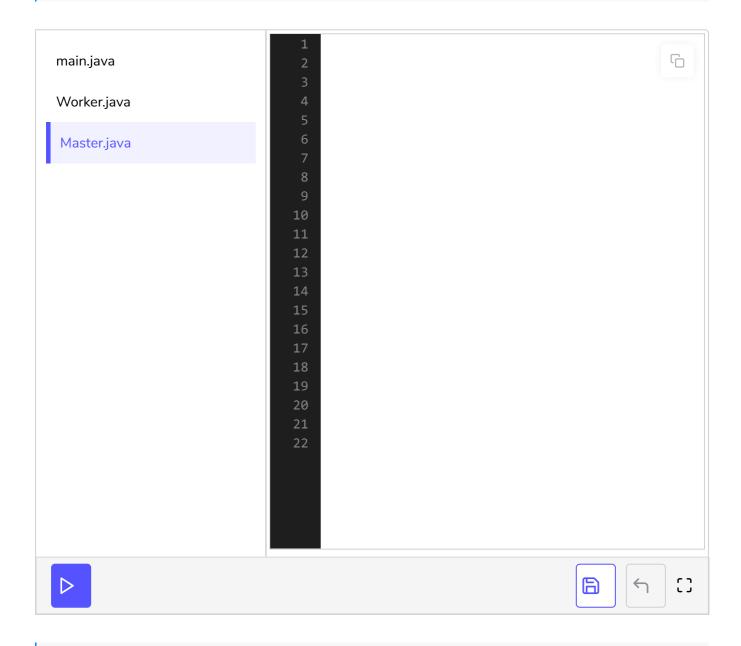

Let's take an example where a master thread waits for worker threads to

complete their execution.

Two workers, A & B, are being executed concurrently (two back to back threads initiated) while the master thread waits for them to finish. Every time a worker completes execution, the counter in the CountDownLatch is decremented by 1. Once all the workers have completed execution, the counter reaches 0 and notifies the threads blocked on the await() method. Subsequently, the latch opens and allows the master thread to run.

```
/**
 * The worker thread that has to complete its tasks first
public class Worker extends Thread
   private CountDownLatch countDownLatch;
   public Worker(CountDownLatch countDownLatch, String name) {
        super(name);
       this.countDownLatch;
   }
   @Override
   public void run()
       System.out.println("Worker " +Thread.currentThread().getName
()+" started");
       try
           Thread.sleep(3000);
       catch (InterruptedException ex)
       {
           ex.printStackTrace();
       System.out.println("Worker "+Thread.currentThread().getName
()+" finished");
       //Each thread calls countDown() method on task completion.
        countDownLatch.countDown();
   }
}
```

```
* The master thread that has to wait for the worker to complete it
s operations first
public class Master extends Thread
    public Master(String name)
    {
        super(name);
    }
   @Override
    public void run()
    {
        System.out.println("Master executed "+Thread.currentThread().
getName());
        try
        {
            Thread.sleep(2000);
        }
        catch (InterruptedException ex)
        {
            ex.printStackTrace();
        }
   }
}
* The main thread that executes both the threads in a particular ord
public class Main
    public static void main(String[] args) throws InterruptedExceptio
n
    {
        //Created CountDownLatch for 2 threads
        CountDownLatch countDownLatch = new CountDownLatch(2);
        //Created and started two threads
        Worker A = new Worker(countDownLatch, "A");
        Worker B = new Worker(countDownLatch, "B");
        A.start();
        B.start();
```

A pictorial representation appears below:

CountDownLaten
